# Package 'quantmod'

January 2, 2012

**Type** Package

**Title** Quantitative Financial Modelling Framework

**Version** 0.3-17

**Date** 2011-06-13

**Author** Jeffrey A. Ryan

**Depends** Defaults, xts(>= 0.7-5), zoo, TTR(>= 0.2), methods

**Suggests** DBI,RMySQL,RSQLite,timeSeries,its

**Maintainer** Jeffrey A. Ryan <jeff.a.ryan@gmail.com>

**Description** Specify, build, trade, and analyse quantitative financial trading strategies

**LazyLoad** yes

**License** GPL-3

**URL** http://www.quantmod.com http://r-forge.r-project.org/projects/quantmod

**Repository** CRAN

**Date/Publication** 2011-08-09 04:59:39

## R topics documented:

---

quantmod-package          *Quantitative Financial Modelling Framework*

---

### Description

Quantitative Financial Modelling and Trading Framework for R

### Details

|  |  |
|---|---|
| Package: | quantmod |
| Type: | Package |
| Version: | 0.3-8 |
| Date: | 2007-11-20 |
| Depends: | xts(>=0.0-15),Defaults |
| Suggests: | DBI,RMySQL,TTR,fSeries,its |
| LazyLoad: | yes |
| License: | GPL-3 |
| URL: | http://www.quantmod.com |
| URL: | http://quantmod.r-forge.r-project.org |

The quantmod package for R is designed to assist the quantitative trader in the development, testing, and deployment of statistically based trading models.

*What quantmod IS*

A rapid prototyping environment, where quant traders can quickly and cleanly explore and build trading models.

*What quantmod is NOT*

A replacement for anything statistical. It has no 'new' modelling routines or analysis tool to speak of. It does now offer charting not currently available elsewhere in R, but most everything else is more of a wrapper to what you already know and love about the langauge and packages you currently use.

quantmod makes modelling easier by removing the repetitive workflow issues surrounding data management, modelling interfaces, and performance analysis.

### Author(s)

Maintainer: Jeffrey A. Ryan <jeff.a.ryan@gmail.com>

---

addADX                        *Add Directional Movement Index*

---

### Description

Add Directional Movement Index

### Usage

```
addADX(n = 14, maType="EMA", wilder=TRUE)
```

### Arguments

| | |
|---|---|
| n | periods to use for DX calculation |
| maType | moving average type |
| wilder | should Welles Wilder EMA be used? |

### Details

See 'ADX' in **TTR** for specific details and references.

### Value

An ADX indicator will be draw in a new window on the current chart. A chobTA object will be returned silently.

### Author(s)

Jeffrey A. Ryan

### References

see ADX in **TTR** written by Josh Ulrich

### See Also

[addTA](#)

### Examples

```
## Not run:
addADX()

## End(Not run)
```

---

| addBBands | *Add Bollinger Bands to Chart* |
|---|---|

---

### Description

Add Bollinger Bands to current chart.

### Usage

```
addBBands(n = 20, sd = 2, maType = "SMA", draw = 'bands', on = -1)
```

### Arguments

| | |
|---|---|
| n | number of moving average periods |
| maType | type of moving average to be used |
| sd | number of standard deviations |
| draw | indicator to draw: bands, percent, or width |
| on | which figure area of chart to apply to |

### Details

The primary addition to this function call over the **TTR** version is in the draw argument. 'bands' will draw standard Bollinger Bands, 'percent' will draw Bollinger %b and 'width' will draw Bolinger Bands Width. The last two will be drawn in new figure regions.

See bollingerBands in **TTR** for specific details as to implementation and references.

### Value

Bollinger Bands will be drawn, or scheduled to be drawn, on the current chart. If draw is either percent or width a new figure will be added to the current TA figures charted.

A chobTA object will be returned silently.

### Author(s)

Jeffrey A. Ryan

### References

See bollingerBands in **TTR** written by Josh Ulrich

## Examples

```
## Not run:
addBBands()

## End(Not run)
```

---

addExpiry                          *Add Contract Expiration Bars to Chart*

---

## Description

Apply options or futures expiration vertical bars to current chart.

## Usage

```
addExpiry(type = "options", lty = "dotted")
```

## Arguments

| | |
|---|---|
| type | options or futures expiration |
| lty | type of lines to draw |

## Details

See options.expiry and futures.expiry in **quantmod** for details and limitations.

## Value

Expiration lines will be drawn at appropriate dates. A chibTA object will be returned silently.

## Author(s)

Jeffrey A. Ryan

## See Also

[addTA](#)

## Examples

```
## Not run:
addExpiry()

## End(Not run)
```

---

addMA                            *Add Moving Average to Chart*

---

### Description

Add one or more moving averages to a chart.

### Usage

```
addSMA(n = 10, on = 1, with.col = Cl, overlay = TRUE, col = "brown")

addEMA(n = 10, wilder = FALSE, ratio=NULL, on = 1,
       with.col = Cl, overlay = TRUE, col = "blue")

addWMA(n = 10, wts=1:n, on = 1, with.col = Cl, overlay = TRUE, col = "green")

addDEMA(n = 10, on = 1, with.col = Cl, overlay = TRUE, col = "pink")

addEVWMA(n = 10, on = 1, with.col = Cl, overlay = TRUE, col = "yellow")

addZLEMA(n = 10, ratio=NULL, on = 1, with.col = Cl, overlay = TRUE, col = "red")
```

### Arguments

| | |
|---|---|
| n | periods to average over |
| wilder | logical; use wilder? |
| wts | a vector of weights |
| ratio | a smoothing/decay ratio |
| on | apply to which figure (see below) |
| with.col | using which column of data (see below) |
| overlay | draw as overlay |
| col | color of MA |

### Details

see the appropriate base MA functions in **TTR** for more details and references.

### Value

A moving average indicator will be draw on the current chart. A chobTA object will be returned silently.

### Author(s)

Jeffrey A. Ryan

## References

see MovingAverages in **TTR** written by Josh Ulrich

## See Also

## Examples

```
## Not run:
addSMA()
addEMA()
addWMA()
addDEMA()
addEVWMA()
addZLEMA()

## End(Not run)
```

---

addMACD                         *Add Moving Average Convergence Divergence to Chart*

---

## Description

Add Moving Average Convergence Divergence indicator to chart.

## Usage

```
addMACD(fast = 12, slow = 26, signal = 9, type = "EMA", histogram = TRUE, col)
```

## Arguments

| | |
|---|---|
| fast | fast period |
| slow | slow period |
| signal | signal period |
| type | type of MA to use. Single values will be replicated |
| histogram | include histogram |
| col | colors to use for lines (optional) |

## Details

See and 'MACD' in **TTR** for specific details and implementation references.

## Value

A MACD indicator will be draw in a new window on the current chart. A chobTA object will be returned silently.

## Author(s)

Jeffrey A. Ryan

## References

see MACD in **TTR** written by Josh Ulrich

## See Also

## Examples

```
## Not run:
addMACD()

## End(Not run)
```

---

addROC                          *Add Rate Of Change to Chart*

---

## Description

Add Rate Of Change indicator to chart.

## Usage

```
addROC(n = 1, type = c("discrete", "continuous"), col = "red")
```

## Arguments

| | |
|---|---|
| n | periods |
| type | compounding type |
| col | line color (optional) |

## Details

See 'ROC' in **TTR** for specific details and references.

## Value

A ROC indicator will be draw in a new window on the current chart. A chobTA object will be returned silently.

## Author(s)

Jeffrey A. Ryan

## References

see ROC in **TTR** written by Josh Ulrich

## See Also

```
## Not run:
addROC()

## End(Not run)
```

---

addRSI                              *Add Relative Strength Index to Chart*

---

## Description

Add a Relative Strength Index indicator to chart.

## Usage

```
addRSI(n = 14, maType = "EMA", wilder = TRUE)
```

## Arguments

| | |
|---|---|
| n | periods |
| maType | type of MA to use |
| wilder | use wilder (see EMA) |

## Details

see 'RSI' in **TTR** for specific details and references.

## Value

An RSI indicator will be draw in a new window on the current chart. A chobTA object will be returned silently.

## Author(s)

Jeffrey A. Ryan

## References

see RSI in **TTR** written by Josh Ulrich

## See Also

[addTA](addTA)

## Examples

```
## Not run:
addRSI()

## End(Not run)
```

---

addSAR                          *Add Parabolic Stop and Reversal to Chart*

---

## Description

Add Parabolic Stop and Reversal indicator overlay to chart.

## Usage

```
addSAR(accel = c(0.02, 0.2), col = "blue")
```

## Arguments

accel          Accelleration factors - see SAR

col            color of points (optional)

## Details

see 'SAR' in **TTR** for specific details and references.

## Value

A SAR overlay will be drawn on the current chart. A chobTA object will be returned silently.

## Author(s)

Jeffrey A. Ryan

## References

see SAR in **TTR** written by Josh Ulrich

## See Also

[addTA](addTA)

## Examples

```
## Not run:
addSAR()

## End(Not run)
```

---

addSMI                        *Add Stochastic Momentum Indicator to Chart*

---

### Description

Add Stochastic Momentum Indicator to chart.

### Usage

```
addSMI(n=13,slow=25,fast=2,signal=9,ma.type="EMA")
```

### Arguments

| | |
|---|---|
| n | periods |
| slow | slow |
| fast | fast |
| signal | signal |
| ma.type | MA tyep to use, recycled as necessary |

### Details

see 'SMI in **TTR** for specifics and references.

### Value

An SMI indicator will be draw in a new window on the current chart. A chobTA object will be returned silently.

### Author(s)

Jeffrey A. Ryan

### References

see SMI in **TTR** written by Josh Ulrich

### See Also

## Examples

```
## Not run:
addSMI()

## End(Not run)
```

---

addVo                    *Add Volume to Chart*

---

### Description

Add Volume of a series, if available, to the current chart. This is the default TA argument for all charting functions.

### Usage

```
addVo(log.scale=FALSE)
```

### Arguments

log.scale        use log-scale for volume

### Details

Add volume bars to current chart if data object contains appropriate volume column.

log.scale will transform the series via standard R graphics mechanisms.

### Value

Volume will be draw in a new window on the current chart. A chobTA object will be returned silently.

### Author(s)

Jeffrey A. Ryan

### See Also

[addTA](#)

### Examples

```
## Not run:
addVo()

## End(Not run)
```

---

## addWPR                          *Add William's Percent R to Chart*

---

### Description

Add William's percent R indiator to the current chart.

### Usage

```
addWPR(n = 14)
```

### Arguments

n                     periods

### Details

see 'WPR' in **TTR** for details and references.

### Value

A William's percent R indicator will be draw in a new window on the current chart. A chobTA
object will be returned silently.

### Author(s)

Jeffrey A. Ryan

### References

see 'WPR' in **TTR** written by Josh Ulrich

### See Also

[addTA](#)

### Examples

```
## Not run:
addWPR()

## End(Not run)
```

| adjustOHLC | *Adjust Open,High,Low,Close Prices For Splits and Dividends* |
|---|---|

### Description

Adjust all columns of an OHLC object for split and dividend.

### Usage

```
adjustOHLC(x,
           adjust = c("split","dividend"),
           use.Adjusted = FALSE,
           ratio = NULL,
           symbol.name=deparse(substitute(x)))
```

### Arguments

| | |
|---|---|
| x | An OHLC object |
| adjust | adjust by split, dividend, or both (default) |
| use.Adjusted | use the 'Adjusted' column in Yahoo! data to adjust |
| ratio | ratio to adjust with, bypassing internal calculations |
| symbol.name | used if x is not named the same as the symbol adjusting |

### Details

This function calculates the adjusted Open, High, Low, and Close prices according to split and dividend information.

There are three methods available to calculate the new OHLC object prices.

By default, getSplits and getDividends are called to retrieve the respective information. These may dispatch to custom methods following the "." methodology used by quantmod dispatch. See getSymbols for information related to extending quantmod. This information is passed to adjSplitDiv from the **TTR** package, and the resulting ratio calculations are used to adjust to observed historical prices. This is the most precise way to adjust a series.

The second method works only on standard Yahoo! data containing an explicit Adjusted column.

A final method allows for one to pass a ratio into the function directly.

All methods proceed as follows:

New columns are derived by taking the ratio of adjusted value to original Close, and multiplying by the difference of the respective column and the original Close. This is then added to the modified Close column to arrive at the remaining 'adjusted' Open, High, Low column values.

If no adjustment is needed, the function returns the original data unaltered.

### Value

An object of the original class, with prices adjusted for splits and dividends.

**Warning**

Using use.Adjusted = TRUE will be less precise than the method that employs actual split and dividend information. This is due to loss of precision from Yahoo! using Adjusted columns of only two decimal places. The advantage is that this can be run offline, and for short series or those with few adjustments the loss of precision will be small.

The resulting precision loss will be from row observation to row observation, as the calculation will be exact for intraday values.

**Author(s)**

Jeffrey A. Ryan

getSymbols.yahoo getSplits getDividends

**Examples**

```
## Not run:
getSymbols("AAPL", from="1990-01-01", src="yahoo")
head(AAPL)
head(AAPL.a <- adjustOHLC(AAPL))
head(AAPL.uA <- adjustOHLC(AAPL, use.Adjusted=TRUE))

# intrada adjustments are precise across all methods
# an example with Open to Close (OpCl)
head(cbind(OpCl(AAPL),OpCl(AAPL.a),OpCl(AAPL.uA)))

# Close to Close changes ma lose precision
head(cbind(ClCl(AAPL),ClCl(AAPL.a),ClCl(AAPL.uA)))

## End(Not run)
```

---

| attachSymbols | *Attach and Flush DDB* |
|---|---|

---

**Description**

Attach a demand database (lazy load) as a new environment.

**Usage**

```
attachSymbols(DB = DDB_Yahoo(),
              pos = 2,
              prefix = NULL,
              postfix = NULL,
              mem.cache = TRUE,
              file.cache = !mem.cache,
              cache.dir = tempdir())

flushSymbols(DB = DDB_Yahoo())
```

**Arguments**

| | |
|---|---|
| DB | A DDB data base object |
| pos | position in search path to attach DB |
| prefix | character to prefix all symbols with |
| postfix | character to postfix all symbols with |
| mem.cache | should objects be cached in memory |
| file.cache | should objects be cached in on disk |
| cache.dir | directory to use for file.cache=TRUE |

**Details**

An experimental function to allow access to remote objects without requiring explicit calls to a loading function.

attachSymbols requires a DDB object to define where the data is to come from, as well as what symbols are loaded on-demand.

attachSymbols calls the method referred to by the DDB object. In the default case this is DDB_Yahoo. See this function for specific details about the Yahoo implementation.

The individual methods make use of getSymbols to load the data. This requires a corresponding getSymbols method.

Internally, attachSymbols makes use of quantmod's unexported create.bindings to dynamically create active bindings to each symbol listed in the DDB object.

In turn, create.bindings uses one of two R methods to create the binding to the names required. This depends on the cache method requested.

Immediately after a call to attachSymbols, a new environment is attached that contains the names of objects yet to be loaded. This is similar to the lazy-load mechanism in R, though extended to be both more general and easier to use.

It is important to note that no data is loaded at this stage. What occurs instead is that these symbols now have active bindings using either delayedAssign (mem.cache) or makeActiveBinding (file.cache).

During all future requests for the object(s) in question, the binding will be used to determine how this data is loaded into R. mem.cache will simply load the data from its corresponding source (as defined by the DDB object) and leave it in the environment specified in the original call. The effect

of this is to allow lazy-loading of data from a variety of external sources (Yahoo in the default case). Once loaded, these are cached in R's memory. Nothing further differentiates these from standard variables. This also means that the environment will grow as more symbols are loaded.

If the `file.cache` option is set, the data is loaded from its source the first time the symbol is referenced. The difference is that the data is then written to a temporary file and maintained there. Data is loaded and subsequently removed upon each request for the object. See `makeActiveBinding` for details of how this occurs at the R level.

A primary advantage of using the file.cache option is the ability to maintain hundreds or thousands of objects in your current session without using memory, or explicitly loading and removing. The main downside of this approach is the that data must be loaded from disk each time, with the corresponding (if generally negligible) overhead of file access.

### Note

This function is new, and all aspects may change in the near future.

### Author(s)

Jeffrey A. Ryan

### References

Luke's stuff and Mark Brevington and Roger Peng

QQQQ
ls()

## End(Not run)
```

---

buildData                        *Create Data Object for Modelling*

---

### Description

Create one data object from multiple sources, applying transformations via standard R formula mechanism.

### Usage

```
buildData(formula, na.rm = TRUE, return.class = "zoo")
```

## Arguments

| | |
|---|---|
| `formula` | an object of class `formula` (or one that can be coerced to that class): a symbolic description of the desired output data object, with the dependent side corresponding to first column, and the `independent` parameters of the formula assigned to the remaining columns. |
| `na.rm` | drop rows with missing values? |
| `return.class` | one of "zoo","data.frame","ts","its","timeSeries" |

## Details

Makes available for use *outside* the **quantmod** workflow a dataset of appropriately transformed variables, using the same mechanism underlying specifyModel. Offers the ability to apply transformations to raw data using a common formula mechanism, without having to explicitly merge different data objects.

Interally calls specifyModel followed by modelData, with the returned object being coerced to the desired 'return.class' if possible, otherwise returns a zoo object.

See getSymbols and specifyModel for more information regarding proper usage.

## Value

An object of class `return.class`.

## Author(s)

Jeffrey A. Ryan

## See Also

[getSymbols](#), [specifyModel](#), [modelData](#)

## Examples

```
## Not run:
  buildData(Next(OpCl(DIA)) ~ Lag(TBILL) + I(Lag(OpHi(DIA))^2))
  buildData(Next(OpCl(DIA)) ~ Lag(TBILL), na.rm=FALSE)
  buildData(Next(OpCl(DIA)) ~ Lag(TBILL), na.rm=FALSE, return.class="ts")

## End(Not run)
```

---

buildModel                    *Build quantmod model given specified fitting method*

---

### Description

Construct and attach a fitted model of type `method` to `quantmod` object.

### Usage

```
buildModel(x, method, training.per, ...)
```

### Arguments

| | |
|---|---|
| x | An object of class quantmod created with [specifyModel](specifyModel) or an R formula |
| training.per | character vector representing dates in ISO 8601 format "CCYY-MM-DD" or "CCYY-MM-DD HH:MM:SS" of length 2 |
| method | A character string naming the fitting method. See details section for available methods, and how to create new methods. |
| ... | Additional arguments to method call |

### Details

Currently available methods include:

lm, glm, loess, step, ppr, rpart[rpart], tree[tree], randomForest[randomForest], mars[mda], polymars[polspline], lars[lars], rq[quantreg], lqs[MASS], rlm[MASS], svm[e1071], and nnet[nnet].

The `training.per` *should* match the undelying date format of the time-series data used in modelling. Any other style may not return what you expect.

Additional methods wrappers can be created to allow for modelling using custom functions. The only requirements are for a wrapper function to be constructed taking parameters `quantmod`, `training.data`, and `...`. The function must return the fitted model object and have a predict method available. It is possible to add predict methods if non exist by adding an S3 method for predictModel. The `buildModel.skeleton` function can be used for new methods.

### Value

An object of class `quantmod` with fitted model attached

### Note

See `buildModel.skeleton` for information on adding additional methods

### Author(s)

Jeffrey Ryan

specifyModel tradeModel

**Examples**

```
## Not run:
getSymbols('QQQQ',src='yahoo')
q.model = specifyModel(Next(OpCl(QQQQ)) ~ Lag(OpHi(QQQQ),0:3))
buildModel(q.model,method='lm',training.per=c('2006-08-01','2006-09-30'))

## End(Not run)
```

---

chartSeries                    *Create Financial Charts*

---

**Description**

Charting tool to create standard financial charts given a time series like object. Serves as the base
function for future technical analysis additions. Possible chart styles include candles, matches (1
pixel candles), bars, and lines. Chart may have white or black background.

reChart allows for dynamic changes to the chart without having to respecify the full chart parameters.

**Usage**

```
chartSeries(x,
            type = c("auto", "candlesticks", "matchsticks", "bars","line"),
            subset = NULL,
            show.grid = TRUE,
            name = NULL,
            time.scale = NULL,
            log.scale = FALSE,
            TA = 'addVo()',
            TAsep=';',
            line.type = "l",
            bar.type = "ohlc",
            theme = chartTheme("black"),
            layout = NA,
            major.ticks='auto', minor.ticks=TRUE,
            yrange=NULL,
            plot=TRUE,
            up.col,dn.col,color.vol = TRUE, multi.col = FALSE,
            ...)

reChart(type = c("auto", "candlesticks", "matchsticks", "bars","line"),
        subset = NULL,
        show.grid = TRUE,
```

```
        name = NULL,
        time.scale = NULL,
        line.type = "l",
        bar.type = "ohlc",
        theme = chartTheme("black"),
        major.ticks='auto', minor.ticks=TRUE,
        yrange=NULL,
        up.col,dn.col,color.vol = TRUE, multi.col = FALSE,
        ...)
```

## Arguments

| | |
|---|---|
| x | an OHLC object - see details |
| type | style of chart to draw |
| subset | xts style date subsetting argument |
| show.grid | display price grid lines? |
| name | name of chart |
| time.scale | what is the timescale? automatically deduced (broken) |
| log.scale | should the y-axis be log-scaled? |
| TA | a vector of technical indicators and params, or character strings |
| TAsep | TA delimiter for TA strings |
| line.type | type of line in line chart |
| bar.type | type of barchart - ohlc or hlc |
| theme | a chart.theme object |
| layout | if NULL bypass internal layout |
| major.ticks | where should major ticks be drawn |
| minor.ticks | should minor ticks be draw? |
| yrange | override y-scale |
| plot | should plot be drawn |
| up.col | up bar/candle color |
| dn.col | down bar/candle color |
| color.vol | color code volume? |
| multi.col | 4 color candle pattern |
| ... | additional parameters |

## Details

Currently displays standard style OHLC charts familiar in financial applications, or line charts when not passes OHLC data. Works with objects having explicit time-series properties.

Line charts are created with close data, or from single column time series.

The subset argument can be used to specify a particular area of the series to view. The underlying series is left intact to allow for TA functions to use the full data set. Additionally, it is possible to use syntax borrowed from the first and last functions, e.g. 'last 4 months'.

TA allows for the inclusion of a variety of chart overlays and tecnical indicators. A full list is available from addTA. The default TA argument is `addVo()` - which adds volume, if available, to the chart being drawn.

`theme` requires an object of class `chart.theme`, created by a call to `chartTheme`. This function can be used to modify the look of the resulting chart. See `chart.theme` for details.

`line.type` and `bar.type` allow further fine tuning of chart styles to user tastes.

`multi.col` implements a color coding scheme used in some charting applications, and follows the following rules:

- grey => Op[t] < Cl[t] and Op[t] < Cl[t-1]
- white => Op[t] < Cl[t] and Op[t] > Cl[t-1]
- red => Op[t] > Cl[t] and Op[t] < Cl[t-1]
- black => Op[t] > Cl[t] and Op[t] > Cl[t-1]

`reChart` takes any number of arguments from the original chart call — and redraws the chart with the updated parameters. One item of note: if multiple color bars/candles are desired, it is necessary to respecify the `theme` argument. Additionally it is not possible to change TA parameters at present. This must be done with addTA/dropTA/swapTA/moveTA commands.

## Value

Returns a standard chart plus volume, if available, suitably scaled.

If `plot=FALSE` a chob object will be returned.

## Note

Most details can be fine-tuned within the function, though the code does a reasonable job of scaling and labelling axes for the user.

The current implementation maintains a record of actions carried out for any particular chart. This is used to recreate the original when adding new indicator. A list of applied TA actions is available with a call to `listTA`. This list can be assigned to a variable and used in new chart calls to recreate a set of technical indicators. It is also possible to force all future charts to use the same indicators by calling `setTA`.

Additional motivation to add outlined candles to allow for scaling and advanced color coding is owed to Josh Ulrich, as are the base functions (from **TTR**) for the yet to be released technical analysis charting code.

Many improvements in the current version were the result of conversations with Gabor Grothendieck. Many thanks to him.

**Examples**

```
## Not run:
getSymbols("YHOO")
chartSeries(YHOO)
chartSeries(YHOO, subset='last 4 months')
chartSeries(YHOO, subset='2007::2008-01')
chartSeries(YHOO,theme=chartTheme('white'))
chartSeries(YHOO,TA=NULL)   #no volume
chartSeries(YHOO,TA=c(addVo(),addBBands()))  #add volume and Bollinger Bands from TTR

addMACD()   #  add MACD indicator to current chart

setTA()
chartSeries(YHOO)   #draws chart again, this time will all indicators present

## End(Not run)
```

---

chartTheme                      *Create A Chart Theme*

---

**Description**

Create a chart.theme object for use within chartSeries to manage desired chart colors.

**Usage**

```
chartTheme(theme = "black", ...)
```

**Arguments**

theme            name of base theme

...              name=value pairs to modify

**Details**

Used as an argument to the chartSeries family of functions, chartTheme allows for on-the-fly modification of pre-specified chart 'themes'. Users can modify a pre-built theme in-place, or copy the theme to a new variable for use in subsequent charting calls.

Internally a chart.theme object is nothing more than a list of values organized by chart components. The primary purpose of this is to facilitate minor modification on the fly, as well as provide a template for larger changes.

Setting style arguments for TA calls via chartTheme requires the user to pass the styles as name=value pairs with a name containing the TA call in question. See examples for assistance.

Current components that may be modified with appropriate values:

- fg.colforeground color
- bg.colbackground color
- grid.colgrid color
- borderborder color
- minor.tickminor tickmark color
- major.tickmajor tickmark color
- up.colup bar/candle color
- dn.coldown bar/candle color
- up.up.colup after up bar/candle color
- up.dn.colup after down bar/candle color
- dn.dn.coldown after down bar/candle color
- dn.up.coldown after up bar/candle color
- up.borderup bar/candle border color
- dn.borderdown bar/candle border color
- up.up.borderup after up bar/candle border color
- up.dn.borderup after down bar/candle border color
- dn.dn.borderdown after down bar/candle border color
- dn.up.borderdown after up bar/candle border color

## Value

A chart.theme object

## Author(s)

Jeffrey A. Ryan

## See Also

## Examples

```
chartTheme()
chartTheme('white')
chartTheme('white',up.col='blue',dn.col='red')

# A TA example
chartTheme(addRSI.col='red')

str(chartTheme())
```

---

chart_Series                    *Experimental Charting Version 2*

---

### Description

These are experimental functions for a new version of chartSeries in quantmod. Interface, behavior, and functionality will change.

### Usage

```
chart_Series(x,
             name = deparse(substitute(x)),
             type = "candlesticks",
             subset = "",
             TA = "",
             pars = chart_pars(),
             theme = chart_theme(),
             clev = 0)
```

### Arguments

| | |
|---|---|
| x | time series object |
| name | name for chart |
| type | one of: |
| subset | an ISO8601 style character string indicating date range |
| TA | a character string of semi-colon seperated TA calls. |
| pars | chart parameters |
| theme | chart theme |
| clev | color level (experimental). Indicates the degree of brightness 0 is darkest color. |

### Details

These functions, when complete, will revert back to the original chartSeries naming convention.

### Value

Called for graphical side effects.

### Note

Highly experimental (read: alpha) use with caution.

## Examples

```
showClass("chob")
```

---

chobTA-class          *A Technical Analysis Chart Object*

---

## Description

Internal storage class for handling arbitrary TA objects

## Objects from the Class

Objects of class chobTA are created and returned invisibly through calls to addTA-style functions.

## Slots

call: Object of class "call" ~~

on: Object of class "ANY" ~~

new: Object of class "logical" ~~

TA.values: Object of class "ANY" ~~

name: Object of class "character" ~~

params: Object of class "ANY" ~~

## Methods

**show** signature(object = "chobTA"): ...

## Note

It is of no external vaule to handle chobTA objects directly

## Author(s)

Jeffrey A. Ryan

## See Also

## Examples

```
showClass("chobTA")
```

---

| create.binding | *Create DDB Bindings* |
|---|---|

---

## Description

Internal function used in `attachSymbols` to create active bindings for symbols defined in a `DDB` object.

## Usage

```
create.binding(s,
               lsym,
               rsym,
               gsrc,
               mem.cache = TRUE,
               file.cache = !mem.cache,
               cache.dir = tempdir(),
               envir,...)
```

## Arguments

| | |
|---|---|
| s | symbol name |
| lsym | function to convert to local name (legal R name) |
| rsym | function to convert to remote name (source name) |
| gsrc | corresponds to 'src' arg in getSymbols call |
| mem.cache | cache to memory |
| file.cache | cache to disk |
| cache.dir | directory to cache to/from |
| envir | environment name (character) |
| ... | arguments to pass to getSymbols call |

## Details

Low level function to create bindings during initial demand-database construction.

## Value

Called for its side effect of creating active bindings to symbols.

## Note

This is code used internally by attachSymbols. User's may modify this to accomodate different systems. The upstream functions needn't maintain consistency with this interface.

Use as a guide or template.

Delt                                            *Calculate Percent Change*

---

## Description

Calculate the k-period percent difference within one series, or between two series. Primarily used to calculate the percent change from one period to another of a given series, or to calculate the percent difference between two series over the full series.

## Usage

```
Delt(x1, x2 = NULL, k = 0, type = c("arithmetic", "log"))
```

## Arguments

| | |
|---|---|
| x1 | *m x 1* vector |
| x2 | *m x 1* vector |
| k | change over k-periods. default k=1 when x2 is NULL. |
| type | type of difference. log or arithmetic (defauly). |

## Details

When called with only x1, the one period percent change of the series is returned by default. Internally this happens by copying x1 to x2. A two period difference would be specified with k=2.

If called with both x1 and x2, the difference between the two is returned. That is, k=0. A one period difference would be specified by k=1. k may also be a vector to calculate more than one period at a time. The results will then be an m x length(k)

Log differences are used by default: Lag = log(x2(t)/x1(t-k))

Arithmetic differences are calculated: Lag = (x2(t) - x1(t-k))/x1(t-k)

## Value

An matrix of length(x1) rows and length(k) columns.

## Author(s)

Jeffrey A. Ryan

## See Also

[OpOp](#) [OpCl](#)

## Examples

```
Stock.Open <- c(102.25,102.87,102.25,100.87,103.44,103.87,103.00)
Stock.Close <- c(102.12,102.62,100.12,103.00,103.87,103.12,105.12)

Delt(Stock.Open)                  #one period pct. price change
Delt(Stock.Open,k=1)              #same
Delt(Stock.Open,type='arithmetic') #using arithmetic differences

Delt(Stock.Open,Stock.Close)      #Open to Close pct. change
Delt(Stock.Open,Stock.Close,k=0:2) #...for 0,1, and 2 periods
```

---

findPeaks *Find Peaks and Valleys In A Series*

---

## Description

Functions to find the peaks (tops) and valleys (bottoms) of a given series.

## Usage

```
findPeaks(x, thresh=0)
findValleys(x, thresh=0)
```

## Arguments

| | |
|---|---|
| x | a time series or vector |
| thresh | minimum peak/valley threshold |

## Value

A vector of integers corresponding to peaks/valleys.

As a peak[valley] is defined as the highest[lowest] value in a series, the function can only define it after a change in direction has occurred. This means that the function will always return the first period *after* the peak/valley of the data, so as not to accidentally induce a look-ahead bias.

## Author(s)

Jeffrey A. Ryan

## Examples

```
findPeaks(sin(1:10))

p <- findPeaks(sin(seq(1,10,.1)))
sin(seq(1,10,.1))[p]

plot(sin(seq(1,10,.1))[p])
plot(sin(seq(1,10,.1)),type='l')
points(p,sin(seq(1,10,.1))[p])
```

---

fittedModel                     *quantmod Fitted Objects*

---

## Description

Extract and replace fitted models from quantmod objects built with buildModel. All objects fitted through methods specified in buildModel calls can be extracted for further analysis.

## Usage

```
fittedModel(object)

## S3 method for class 'quantmod'
formula(x, ...)

## S3 method for class 'quantmod'
plot(x, ...)

## S3 method for class 'quantmod'
coefficients(object, ...)

## S3 method for class 'quantmod'
coef(object, ...)

## S3 method for class 'quantmod'
residuals(object, ...)

## S3 method for class 'quantmod'
resid(object, ...)

## S3 method for class 'quantmod'
fitted.values(object, ...)

## S3 method for class 'quantmod'
fitted(object, ...)
```

```
## S3 method for class 'quantmod'
anova(object, ...)

## S3 method for class 'quantmod'
logLik(object, ...)

## S3 method for class 'quantmod'
vcov(object, ...)
```

## Arguments

object      a quantmod object

x           a suitable object

...         additional arguments

## Details

Most often used to extract the final fitted object of the modelling process, usually for further analysis with tools outside the **quantmod** package.

Most common methods to apply to fitted objects are available to the parent quantmod object. At present, one can call directly the following S3 methods on a built model as if calling directly on the fitted object. See *Usage* section.

It is also *possible* to add a fitted model to an object. This may be of value when applying heuristic rule sets for trading approaches, or when fine tuning already fit models by hand.

## Value

Returns an object matching that returned by a call to the method specified in buildModel.

## Note

The replacement function fittedModel<- is highly experimental, and may or may not continue into further releases.

The fitted model added *must* use the same names as appear in the quantmod object's dataset.

## End(Not run)
```

---

getDividends                *Load Financial Dividend Data*

---

**Description**

Download, or download and append stock dividend data from Yahoo! Finance.

**Usage**

```
getDividends(Symbol,
             from = "1970-01-01",
             to = Sys.Date(),
             env = .GlobalEnv,
             src = "yahoo",
             auto.assign = FALSE,
             auto.update = FALSE,
             verbose = FALSE, ...)
```

**Arguments**

| | |
|---|---|
| Symbol | The Yahoo! stock symbol |
| from | date from in CCYY-MM-DD format |
| to | date to in CCYY-MM-DD format |
| env | where to create object |
| src | data source (only yahoo is valid at present) |
| auto.assign | should results be loaded to env |
| auto.update | automatically add dividend to data object |
| verbose | display status of retrieval |
| ... | currently unused |

**Details**

Eventually destined to be a wrapper function along the lines of `getSymbols` to different sources - this currently only support Yahoo data.

**Value**

If auto.assign is TRUE, the symbol will be written to the environment specified in `env` with a .div appended to the name.

If auto.update is TRUE and the object is of class `xts`, the dividends will be included as an attribute of the original object and be reassigned to the environment specified by `env`.

All other cases will return the dividend data as an `xts` object.

**Note**

This function is very preliminary - and will most likely change significantly in the future.

**Author(s)**

Jeffrey A. Ryan

**Examples**

```
## Not run:
getSymbols("MSFT")
getDividends("MSFT")

getDividends(MSFT)

## End(Not run)
```

---

getFinancials            *Download and View Financial Statements*

---

**Description**

Download Income Statement, Balance Sheet, and Cash Flow Statements from Google Finance.

## Usage

```
getFinancials(Symbol, env = .GlobalEnv, src = "google",
              auto.assign = TRUE,
              ...)

viewFinancials(x, type=c('BS','IS','CF'), period=c('A','Q'),
               subset = NULL)
```

## Arguments

| | |
|---|---|
| Symbol | one or more valid google symbol, as a character vector or semi-colon delimited string |
| env | where to create the object |
| src | currently unused |
| auto.assign | should results be loaded to the environment |
| ... | currently unused |
| x | an object of class financials |
| type | type of statement to view |
| period | period of statement to view |
| subset | 'xts' style subset string |

## Details

A utility to download financial statements for publically traded companies. The data is directly from Google finance. All use of the data is under there Terms of Service, available at http://www.google.com/accounts/TOS.

Individual statements can be accessed using standard R list extraction tools, or by using viewFinancials.

viewFinancials allows for the use of date subsetting as available in the **xts** package, as well as the specification of the type of statement to view. BS for balance sheet, IS for income statement, and CF for cash flow statement. The period argument is used to identify which statements to view - (A) for annual and (Q) for quarterly.

## Value

Six individual matricies organized in a list of class 'financials':

| | |
|---|---|
| IS | a list containing (Q)uarterly and (A)nnual Income Statements |
| BS | a list containing (Q)uarterly and (A)nnual Balance Sheets |
| CF | a list containing (Q)uarterly and (A)nnual Cash Flow Statements |

## Note

As with all free data, you may be getting exactly what you pay for.

## Author(s)

## Examples

```
## Not run:
getFinancials('JAVA')  # returns JAVA.f to "env"
getFin('AAPL') # returns AAPL.f to "env"

viewFin(JAVA.f, "IS", "Q")  # Quarterly Income Statement
viewFin(AAPL.f, "CF", "A")   # Annual Cash Flows

str(AAPL.f)

## End(Not run)
```

---

getFX                              *Download Exchange Rates*

---

## Description

Download exchange rates or metals prices from oanda.

## Usage

```
getFX(Currencies,
      from = Sys.Date() - 500,
      to = Sys.Date(),
      env = .GlobalEnv,
      verbose = FALSE,
      warning = TRUE,
      auto.assign = TRUE, ...)
```

## Arguments

| | |
|---|---|
| Currencies | Currency pairs expressed as 'CUR/CUR' |
| from | start date expressed in ISO CCYY-MM-DD format |
| to | end date expressed in ISO CCYY-MM-DD format |
| env | which environment should they be loaded into |
| verbose | be verbose |
| warning | show warnings |
| auto.assign | use auto.assign |
| ... | additional parameters to be passed to getSymbols.oanda method |

## Details

A convenience wrapper to getSymbols(x,src='oanda'). See getSymbols and getSymbls.oanda for more detail.

## Value

The results of the call will be the data will be assigned automatically to the environment specified (global by default). Additionally a vector of downloaded symbol names will be returned.

See getSymbols and getSymbols.oanda for more detail.

## Author(s)

Jeffrey A. Ryan

## References

## Examples

```
## Not run:

getFX("USD/JPY")

getFX("EUR/USD",from="2005-01-01")

## End(Not run)
```

---

getMetals                     *Download Daily Metals Prices*

---

## Description

Download daily metals prices from oanda.

## Usage

```
getMetals(Metals,
      from = Sys.Date() - 500,
      to = Sys.Date(),
      base.currency="USD",
      env = .GlobalEnv,
      verbose = FALSE,
      warning = TRUE,
      auto.assign = TRUE, ...)
```

## Arguments

| | |
|---|---|
| `Metals` | metals expressed in common name or symbol form |
| `from` | start date expressed in ISO CCYY-MM-DD format |
| `to` | end date expressed in ISO CCYY-MM-DD format |
| `base.currency` | which currency should the price be in |
| `env` | which environment should they be loaded into |
| `verbose` | be verbose |
| `warning` | show warnings |
| `auto.assign` | use auto.assign |
| `...` | additional parameters to be passed to getSymbols.oanda method |

## Details

A convenience wrapper to `getSymbols(x,src='oanda')`.

The most useful aspect of getMetals is the ablity to specify the Metals in terms of underlying 3 character symbol or by name (e.g. XAU (gold) , XAG (silver), XPD (palladium), or XPT (platinum)).

There are unique aspects of any continuously traded commodity, and it is recommended that the user visit <http://www.oanda.com> for details on specific pricing issues.

See `getSymbols` and `getSymbls.oanda` for more detail.

## Value

Data will be assigned automatically to the environment specified (global by default). If auto.assign is set to FALSE, the data from a single metal request will simply be returned from the function call.

If auto.assign is used (the default) a vector of downloaded symbol names will be returned.

See `getSymbols` and `getSymbols.oanda` for more detail.

```

---

getModelData                    *Update model's dataset*

---

## Description

Update currently specified or built model with most recent data.

## Usage

```
getModelData(x, na.rm = TRUE)
```

## Arguments

| | |
|---|---|
| x | An object of class `quantmod` |
| na.rm | Boolean. Remove NA values. Defaults to TRUE |

## Details

Primarily used within specify model calls, `getModelData` is used to retrieve the appropriate underlying variables, and apply model specified transformations automatically. It can be used to also update a current model in memory with the most recent data.

## Value

Returns object of class `quantmod.OHLC`

## Author(s)

Jeffrey Ryan

```

---

getOptionChain          *Download Option Chains*

---

## Description

Function to download option chain data from data providers.

## Usage

```
getOptionChain(Symbols, Exp = NULL, src="yahoo", ...)
```

## Arguments

| | |
|---|---|
| Symbols | The name of the underlying symbol |
| Exp | One or more expiration dates, or NULL. If Exp is missing, the default is to only return the front month contract. |
| src | Source of data. Currently only 'yahoo' is provided |
| ... | additional parameters |

## Details

This function is a wrapper to data-provider specific APIs. By default the data is sourced from yahoo.

## Value

A named list containing two data.frames, one for calls and one for puts. If more than one expiration was requested, this two-element list will be contained within list of length length(Exp). Each element of this list will be named with the expiration month and year (for Yahoo sourced data).

If Exp is set to NULL, all expirations will be returned. Not explicitly setting will only return the front month.

AAPL.OPT <- getOptionChain("AAPL")
AAPL.OPTS <- getOptionChain("AAPL", NULL)

## End(Not run)
```

---

getQuote                          *Download Current Stock Quote*

---

## Description

Fetch current stock quote(s) from specified source. At present this only handle sourcing quotes from Yahoo Finance, but it will be extended to additional sources over time.

## Usage

```
getQuote(Symbols, src = "yahoo", what = standardQuote(), ...)

standardQuote(src="yahoo")
yahooQF(names)
yahooQuote.EOD
```

## Arguments

| | |
|---|---|
| Symbols | character string of symbols, seperated by semi-colons |
| src | source of data (only yahoo is implemented) |
| what | what should be retrieved |
| names | which data should be retrieved |
| ... | currently unused |

## Value

A maximum of 200 symbols may be requested per call to Yahoo!, and all requested will be returned in one data.frame object. If more that 200 symbols are requested, multiple 200 symbol calls will be made and the results will be returned as one data object.

getQuote returns a data frame with rows matching the number of Symbols requested, and the columns matching the requested columns.

The what argument allows for specific data to be requested from yahoo, using Yahoo!'s formatting string. A list and interactive selection tool can be seen with yahooQF.

standardQuote currently only applied to Yahoo! data, and returns an object of class quoteFormat, for use within the getQuote function.

yahooQuote.EOD is a constant that returns OHLCV data

```

---

getSplits                          *Load Financial Split Data*

---

## Description

Download, or download and append stock split data from Yahoo! Finance.

## Usage

```
getSplits(Symbol,
          from = "1970-01-01",
          to = Sys.Date(),
          env = .GlobalEnv,
          src = "yahoo",
          auto.assign = FALSE,
          auto.update = FALSE,
          verbose = FALSE, ...)
```

## Arguments

| | |
|---|---|
| Symbol | The Yahoo! stock symbol |
| from | date from in CCYY-MM-DD format |
| to | date to in CCYY-MM-DD format |
| env | where to create object |
| src | data source (only yahoo is valid at present) |

| auto.assign | should results be loaded to env |
| auto.update | automatically add split to data object |
| verbose | display status of retrieval |
| ... | currently unused |

## Details

Eventually destined to be a wrapper function along the lines of `getSymbols` to different sources - this currently only support Yahoo data.

## Value

If auto.assign is TRUE, the symbol will be written to the environment specified in `env` with a .div appended to the name.

If auto.update is TRUE and the object is of class `xts`, the dividends will be included as an attribute of the original object and be reassigned to the environment specified by `env`.

All other cases will return the split data as an `xts` object. NA is returned if there is no split data.

## Note

This function is very preliminary - and will most likely change significantly in the future.

---

getSymbols *Load and Manage Data from Multiple Sources*

---

### Description

Functions to load and manage Symbols in specified environment. Used by [specifyModel](#) to retrieve symbols specified in first step of modelling procedure. Not a true S3 method, but methods for different data sources follow an S3-like naming convention. Additional methods can be added by simply adhering to the convention.

Current src methods available are: yahoo, google, MySQL, FRED, csv, RData, and oanda.

Data is loaded silently *without* user assignment by default.

### Usage

```
getSymbols(Symbols = NULL,
            env = .GlobalEnv,
            reload.Symbols = FALSE,
            verbose = FALSE,
            warnings = TRUE,
            src = "yahoo",
            symbol.lookup = TRUE,
            auto.assign = TRUE,
            ...)

loadSymbols(Symbols = NULL,
            env = .GlobalEnv,
            reload.Symbols = FALSE,
            verbose = FALSE,
            warnings = TRUE,
            src = "yahoo",
            symbol.lookup = TRUE,
            auto.assign = TRUE,
            ...)

showSymbols(env=.GlobalEnv)
removeSymbols(Symbols=NULL,env=.GlobalEnv)
saveSymbols(Symbols = NULL,
            file.path=stop("must specify 'file.path'"),
            env = .GlobalEnv)
```

### Arguments

| | |
|---|---|
| Symbols | a character vector specifying the names of each symbol to be loaded |
| env | where to create objects. (new.env()) |
| reload.Symbols | boolean to reload current symbols in specified environment. (FALSE) |

| verbose | boolean to turn on status of retrieval. (FALSE) |
|---|---|
| warnings | boolean to turn on warnings. (TRUE) |
| src | character string specifying sourcing method. (yahoo) |
| symbol.lookup | retrieve symbol's sourcing method from external lookup (TRUE) |
| auto.assign | should results be loaded to the environment |
| file.path | character string of file location |
| ... | additional parameters |

### Details

getSymbols is a wrapper to load data from different sources - be them local or remote. Data is fetched through one of the available getSymbols methods and saved in the env specified - the .GlobalEnv by default. Data is loaded in much the same way that load behaves. By default, it is assigned automatically to a variable in the specified environment, *without* the user explicitly assigning the returned data to a variable.

The previous sentence's point warrants repeating - getSymbols is called for its side effects, and *does not* return the data object loaded. The data is 'loaded' silently by the function into a new environment by default - or the environment specified. This behavior can be overridden by setting auto.assign to FALSE, though it is not advised.

Previous versions of getSymbols assigned each object into the user's .GlobalEnv by name. This behavior is now supported by setting env=.GlobalEnv (the current transitional default), or by using the wrapper loadSymbols. Many thanks to Kurt Hornik and Achim Zeileis for suggesting this change.

By default the variable chosen is an R-legal name derived from the symbol being loaded. It is possible, using setSymbolLookup to specify an alternate name if the default is not desired, see that function for details.

The result of a call to getSymbols when auto.assign is set to TRUE (the default) is a new object or objects in the user's specified environment - with the loaded symbol(s) names returned upon exit if that environment is the .GlobalEnv.

By default, a new environment is returned which contains all the objects loaded into it.

If auto.assign is set to FALSE the data will be returned from the call, and will require the user to assign the results himself.

Most, if not all, documentation and functionality in **quantmod** assumes that auto.assign remains set to TRUE.

Upon completion a list of loaded symbols is stored in the global environment under the name .getSymbols.

Objects loaded by getSymbols with auto.assign=TRUE can be viewed with showSymbols and removed by a call to removeSymbols. Additional data loading "methods" can be created simply by following the S3-like naming convention where getSymbols.NAME is used for your function NAME. See getSymbols source code.

setDefaults(getSymbols) can be used to specify defaults for getSymbols arguments. setDefaults(getSymbols.MySQL) may be used for arguments specific to getSymbols.MySQL, etc.

The "sourcing" of data is managed internally through a complex lookup procedure. If symbol.lookup is TRUE (the default), a check is made if any symbol has had its source specified by setSymbolLookup.

If not set, the process continues by checking to see if src has been specified by the user in the function call. If not, any src defined with setDefaults(getSymbols,src=) is used.

Finally, if none of the other source rules apply the default getSymbols src method is used ('yahoo').

### Value

A call to getSymbols will load into the specified environment one object for each Symbol specified, with class defined by return.class. Presently this may be ts, its, zoo, xts, or timeSeries.

If auto.assign is set to FALSE an object of type return.class will be returned.

### Note

While it is possible to load symbols as classes other than zoo, **quantmod** requires most, if not all, data to be of class zoo or inherited from zoo - e.g. xts. The additional methods are meant mainly to be of use for those using the functionality outside of the **quantmod** workflow.

getModelData, specifyModel, setSymbolLookup, getSymbols.csv, getSymbols.RData, getSymbols.oanda, getSymbols.yahoo, getSymbols.google, getSymbols.FRED, getFX, getMetals,

### Examples

```
## Not run:
setSymbolLookup(QQQQ='yahoo',SPY='MySQL')

getSymbols(c('QQQQ','SPY'))
# loads QQQQ from yahoo (set with setSymbolLookup)
# loads SPY from MySQL (set with setSymbolLookup)

getSymbols('F')
# loads Ford market data from yahoo (the formal default)

setDefaults(getSymbols,verbose=TRUE,src='MySQL')
getSymbols('DIA')
# loads symbol from MySQL database (set with setDefaults)

getSymbols('F',src='yahoo',return.class='ts')
# loads Ford as time series class ts

## End(Not run)
```

---

getSymbols.csv                      *Load Data from csv File*

---

### Description

Downloads Symbols to specified env from local comma seperated file. This method is not to be
called directly, instead a call to getSymbols(Symbols,src='csv') will in turn call this method. It
is documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide
to creating additional getSymbols 'methods'.

### Usage

```
getSymbols.csv(Symbols,
                 env,
                 dir="",
                 return.class = "xts",
                 extension="csv",
                  ...)
```

### Arguments

| | |
|---|---|
| Symbols | a character vector specifying the names of each symbol to be loaded |
| env | where to create objects. (.GlobalEnv) |
| dir | directory of csv file |
| return.class | class of returned object |
| extension | extension of csv file |
| ... | additional parameters |

### Details

Meant to be called internally by getSymbols (see also).

One of a few currently defined methods for loading data for use with **quantmod**. Essentially a
simple wrapper to the underlying R read.csv.

### Value

A call to getSymbols.csv will load into the specified environment one object for each Symbol speci-
fied, with class defined by return.class. Presently this may be ts, its, zoo, xts, or timeSeries.

### Note

This has yet to be tested on a windows platform. It *should* work though file seperators may be an
issue.

## End(Not run)
```

---

getSymbols.FRED          *Download Federal Reserve Economic Data - FRED(R)*

---

**Description**

R access to over 11,000 data series accessible via the St. Louis Federal Reserve Bank's FRED system.

Downloads Symbols to specified env from 'research.stlouisfed.org'. This method is not to be called directly, instead a call to getSymbols(Symbols,src='FRED') will in turn call this method. It is documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide to creating additional getSymbols 'methods'.

**Usage**

```
getSymbols.FRED(Symbols,
                env,
                return.class = "xts",
                ...)
```

**Arguments**

| | |
|---|---|
| `Symbols` | a character vector specifying the names of each symbol to be loaded |
| `env` | where to create objects. (.GlobalEnv) |
| `return.class` | class of returned object |
| `...` | additional parameters |

**Details**

Meant to be called internally by `getSymbols` (see also).

One of many methods for loading data for use with **quantmod**. Essentially a simple wrapper to the underlying FRED data download site.

Naming conventions must follow those as seen on the Federal Reserve Bank of St Louis's website for FRED. A lookup facility will hopefully be incorporated into **quantmod** in the near future.

**Value**

A call to getSymbols.FRED will load into the specified environment one object for each Symbol specified, with class defined by return.class. Presently this may be `ts`, `its`, `zoo`, `xts`, or `timeSeries`.

getSymbols('CPIAUCNS',src='FRED')
```

```
## Method #2
setDefaults(getSymbols,src='FRED')
  # OR
setSymbolLookup(CPIAUCNS='FRED')

getSymbols('CPIAUCNS')

###########################################
##   NOT RECOMMENDED!!!
###########################################
## Method #3
getSymbols.FRED('CPIAUCNS',env=globalenv())

## End(Not run)
```

---

getSymbols.google          *Download OHLC Data From Google Finance*

---

### Description

Downloads Symbols to specified env from 'finance.google.com'. This method is not to be called directly, instead a call to getSymbols(Symbols,src='google') will in turn call this method. It is documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide to creating additional getSymbols 'methods'.

### Usage

```
getSymbols.google(Symbols,
                  env,
                  return.class = 'xts',
                  from = "2007-01-01",
                  to = Sys.Date(),
                  ...)
```

### Arguments

| | |
|---|---|
| Symbols | a character vector specifying the names of each symbol to be loaded |
| env | where to create objects. (.GlobalEnv) |
| return.class | class of returned object |
| from | Retrieve no earlier than this date |
| to | Retrieve though this date |
| ... | additional parameters |

**Details**

Meant to be called internally by `getSymbols` (see also).

One of a few currently defined methods for loading data for use with **quantmod**. Essentially a simple wrapper to the underlying Google Finance site for historical data.

A word of warning. Google is the home of *BETA*, and historic data is no exception. There is a *BUG* in practically all series that include the dates Dec 29,30, and 31 of 2003. The data will show the wrong date and corresponding prices. This essentially makes it useless, but if they ever apply a fix the data is nice(r) than Yahoo, in so much as it is all split adjusted and there is forty years worth to be had. As long as you skip the holiday week of 2003. : )

**Value**

A call to getSymbols.google will load into the specified environment one object for each Symbol specified, with class defined by `return.class`. Presently this may be `ts`, `its`, `zoo`, `xts`, or `timeSeries`.

**Note**

As mentioned in the details section, a serious flaw exists within the google database/SQL. A caution is issued when retrieving data via this method if this particular error is encountered, but one can only wonder what else may be wrong. Caveat emptor.

```

---

getSymbols.MySQL            *Retrieve Data from MySQL Database*

---

## Description

Fetch data from MySQL database. As with other methods extending the `getSymbols` function, this should *NOT* be called directly. Its documentation is meant to highlight the formal arguments, as well as provide a reference for further user contributed data tools.

## Usage

```
getSymbols.MySQL(Symbols,
                 env,
                 return.class = 'xts',
                 db.fields = c("date", "o", "h", "l", "c", "v", "a"),
                 field.names = NULL,
                 user = NULL,
                 password = NULL,
                 dbname = NULL,
                 ...)
```

## Arguments

| | |
|---|---|
| `Symbols` | a character vector specifying the names of each symbol to be loaded |
| `env` | where to create objects. (.GlobalEnv) |
| `return.class` | desired class of returned object. Can be xts, zoo, data.frame, ts, or its. (zoo) |
| `db.fields` | character vector indicating names of fields to retrieve |
| `field.names` | names to assign to returned columns |
| `user` | username to access database |
| `password` | password to access database |
| `dbname` | database name |
| `...` | currently not used |

**Details**

Meant to be called internally by `getSymbols` (see also)

One of a few currently defined methods for loading data for use with **quantmod**. Its use requires the packages **DBI** and **MySQL**, along with a running MySQL database with tables corresponding to the Symbol name.

The purpose of this abstraction is to make transparent the 'source' of the data, allowing instead the user to concentrate on the data itself.

**Value**

A call to getSymbols.MySQL will load into the specified environment one object for each Symbol specified, with class defined by `return.class`.

**Note**

The default configuration needs a table named for the Symbol specified (e.g. MSFT), with column names date,o,h,l,c,v,a. For table layout changes it is best to use `setDefaults(getSymbols.MySQL,...)` with the new db.fields values specified.

## Method #3
getSymbols.MySQL('MSFT',env=globalenv())

## End(Not run)
```

---

getSymbols.oanda          *Download Currency and Metals Data from Oanda.com*

---

### Description

Access to 191 currency and metal prices, downloadable as more that 36000 currency pairs from Oanda.com.

Downloads Symbols to specified env from <www.oanda.com> historical currency database. This method is not meant to be called directly, instead a call to getSymbols("x",src="oanda") will in turn call this method. It is documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide to creating additional getSymbols 'methods'.

### Usage

```
getSymbols.oanda(Symbols,
                 env,
                 return.class = "xts",
                 from = Sys.Date() - 499,
                 to = Sys.Date(),
                 ...)
```

### Arguments

| | |
|---|---|
| Symbols | a character vector specifying the names of each symbol to be loaded - expressed as a currency pair. (e.g. U.S. Dollar to Euro rate would be expressed as a string "USD/EUR". The naming convention follows from Oanda.com, and a table of possible values is available by calling oanda.currencies |
| env | where to create objects. |
| return.class | class of returned object |
| from | Start of series expressed as "CCYY-MM-DD" |
| to | Start of series expressed as "CCYY-MM-DD" |
| ... | additional parameters |

**Details**

Meant to be called internally by getSymbols only.

Oanda data is 7 day daily average price data, that is Monday through Sunday. There is a limit of 500 days per request, and getSymbols will fail with a warning that the limit has been exceeded.

**Value**

A call to getSymbols(Symbols,src="oanda") will load into the specified environment one object for each 'Symbol' specified, with class defined by 'return.class'. Presently this may be 'ts', 'its', 'zoo', 'xts', or 'timeSeries'.

**Note**

Oanda rates are quoted as one unit of base currency to the equivelant amount of foreign currency.

## End(Not run)
```

---

getSymbols.rda              *Load Data from R Binary File*

---

**Description**

Downloads `Symbols` to specified env from local R data file. This method is not to be called directly, instead a call to `getSymbols(Symbols,src='rda')` will in turn call this method. It is documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide to creating additional getSymbols 'methods'.

## Usage

```
getSymbols.rda(Symbols,
                env,
                dir="",
                return.class = "xts",
                extension="rda",
                col.names=c("Open","High","Low","Close","Volume","Adjusted"),
                ...)
```

## Arguments

| | |
|---|---|
| Symbols | a character vector specifying the names of each symbol to be loaded |
| env | where to create objects. (.GlobalEnv) |
| dir | directory of rda/RData file |
| return.class | class of returned object |
| extension | extension of R data file |
| col.names | data column names |
| ... | additional parameters |

## Details

Meant to be called internally by `getSymbols` (see also).

One of a few currently defined methods for loading data for use with **quantmod**. Essentially a simple wrapper to the underlying R `load`.

## Value

A call to getSymbols.csv will load into the specified environment one object for each Symbol specified, with class defined by `return.class`. Presently this may be ts, its, zoo, xts, data.frame, or timeSeries.

getSymbols.SQLite          *Retrieve Data from SQLite Database*

---

### Description

Fetch data from SQLite database. As with other methods extending getSymbols this function
should *NOT* be called directly.

### Usage

```
getSymbols.SQLite(Symbols,
                  env,
                  return.class = 'xts',
                  db.fields = c("row_names",
                                "Open",
                                "High",
                                "Low",
                                "Close",
                                "Volume",
                                "Adjusted"),
                  field.names = NULL,
                  dbname = NULL,
                  POSIX = TRUE,
                  ...)
```

### Arguments

Symbols          a character vector specifying the names of each symbol to be loaded

| env | where to create the objects |
|---|---|
| return.class | desired class of returned object |
| db.fields | character vector naming fields to retrieve |
| field.names | names to assign to returned columns |
| dbname | database name |
| POSIX | are rownames numeric |
| ... | additional arguments |

## Details

Meant to be called internally by `getSymbols` (see also)

One of a few currently defined methods for loading data for use with 'quantmod'. Its use requires the packages 'DBI' and 'RSQLite', along with a SQLite database.

The purpose of this abstraction is to make transparent the 'source' of the data, allowing instead the user to concentrate on the data itself.

## Value

A call to getSymbols.SQLite will load into the specified environment one object for each 'Symbol' specified, with class defined by 'return.class'.

## Note

This function is experimental at best, and has not been thoroughly tested. Use with caution, and please report any bugs to the maintainer of quantmod.

getSymbols.yahoo                    *Download OHLC Data From Yahoo Finance*

---

**Description**

Downloads Symbols to specified env from 'finance.yahoo.com'. This method is not to be called
directly, instead a call to getSymbols(Symbols,src='yahoo') will in turn call this method. It is
documented for the sole purpose of highlighting the arguments accepted, and to serve as a guide to
creating additional getSymbols 'methods'.

**Usage**

```
getSymbols.yahoo(Symbols,
                 env,
                 return.class = 'xts',
                 index.class  = 'Date',
                 from = "2007-01-01",
                 to = Sys.Date(),
                  ...)
```

**Arguments**

| | |
|---|---|
| Symbols | a character vector specifying the names of each symbol to be loaded |
| env | where to create objects. (.GlobalEnv) |
| return.class | class of returned object |
| index.class | class of returned object index (xts only) |
| from | Retrieve data no earlier than this date. (2007-01-01) |
| to | Retrieve data through this date (Sys.Date()) |
| ... | additional parameters |

**Details**

Meant to be called internally by getSymbols (see also).

One of a few currently defined methods for loading data for use with **quantmod**. Essentially a
simple wrapper to the underlying Yahoo! finance site's historical data download.

**Value**

A call to getSymbols.yahoo will load into the specified environment one object for each Symbol
specified, with class defined by return.class. Presently this may be ts, its, zoo, xts, or
timeSeries.

In the case of xts objects, the indexing will be by Date. This can be altered with the index.class
argument. See indexClass for more information on changing index classes.

---

has.OHLC                          *Check For OHLC Data*

---

## Description

A set of functions to check for appropriate OHLC and HLC column names within a data object, as well as the availability and position of those columns.

## Usage

```
is.OHLC(x)
has.OHLC(x, which = FALSE)

is.OHLCV(x)
has.OHLCV(x, which = FALSE)

is.HLC(x)
has.HLC(x, which = FALSE)

has.Op(x, which = FALSE)
has.Hi(x, which = FALSE)
has.Lo(x, which = FALSE)
has.Cl(x, which = FALSE)
has.Vo(x, which = FALSE)
has.Ad(x, which = FALSE)

is.BBO(x)
is.TBBO(x)

has.Ask(x, which = FALSE)
has.Bid(x, which = FALSE)
has.Price(x, which = FALSE)
has.Qty(x, which = FALSE)
has.Trade(x, which = FALSE)
```

## Arguments

| | |
|---|---|
| x | data object |
| which | disply position of match |

## Details

Mostly used internally by **quantmod**, they can be useful for checking whether an object can be used in OHLC requiring functions like `Op`, `OpCl`, etc.

Columns names must contain the full description of data, that is, Open, High, Low, Close, Volume or Adjusted. Abbreviations will return FALSE (or NA when which=TRUE). See [quantmod.OHLC](quantmod.OHLC) for details of **quantmod** naming conventions.

`is.OHLC` (and is.HLC, similarly) will only return TRUE is there are columns for Open, High, Low and Close. Additional columns will not affect the value.

## Value

A logical value indicating success or failure by default.

If which=TRUE, a numeric value representing the column position will be returned.

`is.OHLC` and `is.HLC` return a single value of TRUE or FALSE.

---

Lag                                *Lag a Time Series*

---

## Description

Create a lagged series from data, with NA used to fill.

## Usage

```
Lag(x, k = 1)

## S3 method for class 'quantmod.OHLC'
Lag(x, k = 1)

## S3 method for class 'zoo'
Lag(x, k = 1)

## S3 method for class 'data.frame'
Lag(x, k = 1)

## S3 method for class 'numeric'
Lag(x, k = 1)
```

## Arguments

x               vector or series to be lagged
k               periods to lag.

## Details

Shift series k-periods down, prepending NAs to front of series.

Specifically designed to handle quantmod.OHLC and zoo series within the quantmod workflow.

If no S3 method is found, a call to lag in **base** is made.

## Value

The original x prepended with k NAs and missing the trailing k values.

The returned series maintains the number of obs. of the original.

## Note

This function differs from lag by returning the original series modified, as opposed to simply changing the time series properties. It differs from the like named Lag in the **Hmisc** as it deals primarily with time-series like objects.

It is important to realize that if there is no applicable method for Lag, the value returned will be from lag in **base**. That is, coerced to 'ts' if necessary, and subsequently shifted.

## Examples

```
Stock.Close <- c(102.12,102.62,100.12,103.00,103.87,103.12,105.12)
Close.Dates <- as.Date(c(10660,10661,10662,10665,10666,10667,10668),origin="1970-01-01")
Stock.Close <- zoo(Stock.Close,Close.Dates)

Lag(Stock.Close)        #lag by 1 period
Lag(Stock.Close,k=1)    #same
Lag(Stock.Close,k=1:3)  #lag 1,2 and 3 periods
```

---

modelData                    *Extract Dataset Created by specifyModel*

---

## Description

Extract from a quantmod object the dataset created for use in modelling.

specifyModel creates a zoo object for use in subsequent workflow stages ( buildModel,tradeModel) that combines all model inputs, from a variety of sources, into one model frame.

modelData returns this object.

## Usage

```
modelData(x, data.window = NULL, exclude.training = FALSE)
```

## Arguments

x                    a quantmod object

data.window      a character vector of subset start and end dates to return

exclude.training

                 remove training period

## Details

When a model is created by specifyModel, it is attached to the returned object. One of the slots of this S4 class is model.data.

## Value

an object of class zoo containing all transformations to data specified in specifyModel.

## Author(s)

Jeffrey A. Ryan

modelSignal                                *Extract Model Signal Object*

---

## Description

Extract model signal object from quantmodResults object as an object of class zoo.

## Usage

```
modelSignal(x)
```

## Arguments

x                 object of class quantmodResults

## Details

For use after a call to tradeModel to extract the generated signal of a given quantmod model. Normally this would not need to be called by the end user unless he was manually post processing the trade results.

## Value

A zoo object indexed by signal dates.

## Author(s)

newTA                          *Create A New TA Indicator For chartSeries*

---

## Description

Functions to assist in the creation of indicators or content to be drawn on plots produced by chart-Series.

## Usage

```
addTA(ta,
      order = NULL,
      on = NA,
      legend = "auto",
      yrange = NULL,
      ...)

newTA(FUN,
      preFUN,
      postFUN,
      on = NA,
      yrange = NULL,
      legend.name,
      fdots = TRUE,
      cdots = TRUE,
      data.at = 1,
      ...)
```

## Arguments

| | |
|---|---|
| ta | data to be plotted |
| order | which should the columns (if > 1) be plotted |
| legend | what custom legend text should be added to the chart. |
| FUN | Main filter function name - as a symbol |
| preFUN | Pre-filter transformation or extraction function |
| postFUN | Post-filter transformation or extraction function |
| on | where to draw |
| yrange | length 2 vector of y-axis range |

| | |
|---|---|
| legend.name | optional legend heading, automatically derived otherwise |
| fdots | should any ... be included in the main filter call |
| cdots | should any ... be included in the resultant function object. `fdots=TRUE` will override this to TRUE. |
| data.at | which arguement to the main filter function is for data. |
| ... | any additonal graphical parameters/default to be included. |

**Details**

Both `addTA` and `newTA` can be used to dynamically add custom content to a displayed chart.

`addTA` takes a series of values, either in a form coercible to `xts` or of the same length as the charted series has rows, and displays the results in either a new TA sub-window, or over/underlayed on the main price chart. If the object can be coerced to `xts`, the time values present must only be within the original series time-range. Internally a merge of dates occurs and will allow for the plotting of discontinuous series.

The `order` argument allows for multiple column data to be plotted in an order that makes the most visual sense.

Specifying a `legend` will override the standard parsing of the addTA call to attempt a guess at a suitable title for the sub-chart. Specifying this will cause the standard last value to *not* be printed.

The ... arg to `addTA` is used to set graphical parameters interpretable by `lines`.

`newTA` acts as more of a skeleton function, taking functions as arguments, as well as charting parameters, and returns a function that can be called in the same manner as the built-in TA tools, such as `addRSI` and `addMACD`. Essentially a dynamic code generator that allows for highly customizable chart tools with minimal (possibly zero) coding. It is also possible to modify the resultant code to further change behavior.

To create a new TA function with `newTA` certain arguments must be specified.

The `FUN` argument is a function symbol (or coercible to such) that is the primary filter to be used on the core-data of a chartSeries chart. This can be like most of the functions within the **TTR** package — e.g. RSI or EMA. The resultant object of the function call will be equal to calling the function on the original data passed into the chartSeries function that created the chart. It should be coercible to a matrix object, of one or more columns of output. By default all columns of output will be added to the chart, unless suppressed by passing the appropriately positioned type='n' as the ... arg. Note that this will not suppress the labels added to the chart.

The `preFUN` argument will be called on the main chart's data prior to passing it to FUN. This must be a function symbol or a character string of the name function to be called.

The `postFUN` argument will be called on the resultant data returned from the `FUN` filter. This is useful for extracting the relevant data from the returned filter data. Like `preFUN` it must be a function symbol or a character string of the name of the function to be called.

The `yrange` argument is used to provide a custom scale to the y-axis. If NULL the min and max of the data to be plotted will be used for the y-axis range.

The `on` is used to identify which subchart to add the graphic to. By default, on=NA will draw the series in a new subchart below the last indicator. Setting this to either a positive or negative value will allow for the series to be super-imposed on, or under, the (sub)chart specified, respectively. A value of 1 refers to the main chart, and at present is the only location supported.

legend.name will change the main label for a new plot.

fdots and cdots enable inclusion or suppression of the ... within the resulting TA code's call to FUN, or the argument list of the new TA function, respectively. In order to facilitate user-specified graphical parameters it is usually desireable to not impose artificial limits on the end-user with constraints on types of parameters available. By default the new TA function will include the dots argument, and the internal FUN call will keep all arguments, including the dots. This may pose issues if the internal function then passes those ... arguments to a function that can't handle them.

The final argument is data.at which is the position in the FUN argument list which expects the data to be passed in at. This default to the sensible first position, though can be changed at the time of creation by setting this argument to the required value.

While the above functions are usually sufficient to construct very pleasing graphical additions to a chart, it may be necessary to modify by-hand the code produced. This can be accomplished by dumping the function to a file, or using fix on it during an interactive session.

Another item of note, with respect to newTA is the naming of the main legend label. Following addTA convention, the first 'add' is stripped from the function name, and the rest of the call's name is used as the label. This can be overridden by specifying legend.name in the construction of the new TA call, or by passing legend into the new TA function. Subtle differences exist, with the former being the preferred solution.

While both functions can be used to build new indicators without any understanding of the internal chartSeries process, it may be beneficial in more complex cases to have a knowledge of the multi-step process involved in creating a chart via chartSeries.

to be added...

**Value**

addTA will invisibly return an S4 object of class chobTA. If this function is called interactively, the chobTA object will be evaluated and added to the current chart.

newTA will return a function object that can either be assigned or evaluated. Evaluating this function will follow the logic of any standard addTA-style call, returning invisibly a chobTA object, or adding to the chart.

**Note**

Both interfaces are meant to fascilitate custom chart additions. addTA is for adding any arbitrary series to a chart, where-as newTA works with the underlying series with the main chart object. The latter also acts as a dynamic TA skeleton generation tool to help develop reusable TA generation code for use on any chart.

## Examples

```
## Not run:
getSymbols('SBUX')
barChart(SBUX)
addTA(EMA(Cl(SBUX)), on=1, col=6)
addTA(OpCl(SBUX), col=4, type='b', lwd=2)
# create new EMA TA function
newEMA <- newTA(EMA, Cl, on=1, col=7)
newEMA()
newEMA(on=NA, col=5)

## End(Not run)
```

---

Next                        *Advance a Time Series*

---

## Description

Create a new series with all values advanced forward one period. The value of period 1, becomes the value at period 2, value at 2 becomes the original value at 3, etc. The opposite of Lag. NA is used to fill.

## Usage

```
Next(x, k = 1)

## S3 method for class 'quantmod.OHLC'
Next(x,k=1)

## S3 method for class 'zoo'
Next(x,k=1)

## S3 method for class 'data.frame'
Next(x,k=1)

## S3 method for class 'numeric'
Next(x,k=1)
```

## Arguments

x               vector or series to be advanced

k               periods to advance

## Details

Shift series k-periods up, appending NAs to end of series.

Specifically designed to handle `quantmod.OHLC` and `zoo` series within the **quantmod** workflow.

If no S3 method is found, a call to `lag` in **base** is made, with the indexing reversed to shift the time series forward.

## Value

The original `x` appended with k NAs and missing the leading k values.

The returned series maintains the number of obs. of the original.

Unlike `Lag`, only one value for k is allowed.

## Note

This function's purpose is to get the "next" value of the data you hope to forecast, e.g. a stock's closing value at t+1. Specifically to be used within the **quantmod** framework of `specifyModel`, as a functional wrapper to the LHS of the model equation.

It is not magic - and thus will not get tomorrow's values...

## Examples

```
Stock.Close <- c(102.12,102.62,100.12,103.00,103.87,103.12,105.12)
Close.Dates <- as.Date(c(10660,10661,10662,10665,10666,10667,10668),origin="1970-01-01")
Stock.Close <- zoo(Stock.Close,Close.Dates)

Next(Stock.Close)        #one period ahead
Next(Stock.Close,k=1)    #same

merge(Next(Stock.Close),Stock.Close)

## Not run:
# a simple way to build a model of next days
# IBM close, given todays. Technically both
# methods are equal, though the former is seen
# as more intuitive...ymmv
specifyModel(Next(Cl(IBM)) ~ Cl(IBM))
specifyModel(Cl(IBM) ~ Lag(Cl(IBM)))

## End(Not run)
```

---

OHLC.Transformations     *Extract and Transform OHLC Time-Series Columns*

---

**Description**

Extract (transformed) data from a suitable OHLC object. Column names must contain the complete description - either "Open", "High", "Low", "Close", "Volume", or "Adjusted" - though may also contain additional characters. This is the default for objects returned from most `getSymbols` calls.

In the case of functions consisting of combined Op, Hi, Lo, Cl (e.g. `ClCl(x)`) the one period transformation will be applied.

For example, to return the Open to Close of a object it is possible to call `OpCl(x)`. If multiple periods are desired a call to the function `Delt` is necessary.

`seriesLo` and `seriesHi` will return the low and high, respectively, of a given series.

`seriesAccel`, `seriesDecel`, `seriesIncr`, and `seriesDecr`, return a vector of logicals indicating if the series is accellerating, decellerating, increasing, or decreasing. This is managed by `diff`, which provides NA fill and suitable re-indexing. These are here to make trade rules easier to read.

`HLC` extracts the High, Low, and Close columns. `OHLC` extracts the Open, High, Low, and Close columns.

These functions are merely to speed the model specification process. All columns may also be extracted through standard R methods.

Assignment will not work at present.

**Usage**

```
Op(x)
Hi(x)
Lo(x)
Cl(x)
Vo(x)
Ad(x)

seriesHi(x)
seriesLo(x)
seriesIncr(x, thresh=0, diff.=1L)
seriesDecr(x, thresh=0, diff.=1L)

OpCl(x)
ClCl(x)
HiCl(x)
LoCl(x)
LoHi(x)
OpHi(x)
OpLo(x)
OpOp(x)
```

```
HLC(x)
OHLC(x)
```

## Arguments

| | |
|---|---|
| x | A data object with columns containing data to be extracted. |
| thresh | noise threshold (seriesIncr/seriesDecr) |
| diff. | differencing (seriesIncr/seriesDecr) |

## Details

Internally, the code uses grep to locate the appropriate columns. Therefore it is necessary to use inputs with column names matching the requirements in the description section, though the exact naming convention is not as important.

## Value

Returns an object of the same class as the original series, with the appropriately column names if applicable and/or possible. The only exceptions are for quantmod.OHLC objects which will be returned as zoo objects, and calls to seriesLo and seriesHi which *may* return a numeric value instead of the original object type.

---

options.expiry            *Calculate Contract Expirations*

---

### Description

Return the index of the contract expiration date. The third Friday of the month for options, the last third Friday of the quarter for futures.

### Usage

```
options.expiry(x)
futures.expiry(x)
```

### Arguments

x                         a time-indexed zoo object

### Details

Designed to be used within a charting context via addExpiry, the values returned are based on the description above. Exceptions, though rare, are not accounted for.

### Value

A numeric vector of values to index on.

### Note

There is currently no accounting for holidays that may interfere with the general rule. Additionally all efforts have been focused on US equity and futures markets.

---

| periodReturn | *Calculate Periodic Returns* |
| --- | --- |

---

## Description

Given a set of prices, return periodic returns.

## Usage

```
periodReturn(x,
             period='monthly',
             subset=NULL,
             type='arithmetic',
             leading=TRUE,
             ...)

dailyReturn(x, subset=NULL, type='arithmetic',
          leading=TRUE, ...)
weeklyReturn(x, subset=NULL, type='arithmetic',
          leading=TRUE, ...)
monthlyReturn(x, subset=NULL, type='arithmetic',
          leading=TRUE, ...)
quarterlyReturn(x, subset=NULL, type='arithmetic',
          leading=TRUE, ...)
annualReturn(x, subset=NULL, type='arithmetic',
          leading=TRUE, ...)
yearlyReturn(x, subset=NULL, type='arithmetic',
          leading=TRUE, ...)
allReturns(x, subset=NULL, type='arithmetic',
          leading=TRUE)
```

## Arguments

| | |
| --- | --- |
| x | object of state prices, or an OHLC type object |
| period | character string indicating time period. Valid entries are 'daily', 'weekly', 'monthly', 'quarterly', 'yearly'. All are accessible from wrapper functions described below. Defaults to monthly returns (same as monthlyReturn) |

| subset | an xts/ISO8601 style subset string |
| type | type of returns: arithmetic (discrete) or log (continuous) |
| leading | should incomplete leading period returns be returned |
| ... | passed along to to.period |

**Details**

periodReturn is the underlying function for wrappers:

- allReturns:   calculate all available return periods
- dailyReturn:   calculate daily returns
- weeklyReturn:   calculate weekly returns
- monthlyReturn:   calculate monthly returns
- quarterlyReturn:   calculate quarterly returns
- annualReturn:   calculate annual returns

**Value**

Returns object of the class that was originally passed in, with the possible exception of monthly and quarterly return indicies being changed to class yearmon and yearqtr where available. This can be overridden with the indexAt argument passed in the ...to the to.period function.

By default, if subset is NULL, the full dataset will be used.

**Note**

Attempts are made to re-convert the resultant series to its original class, if supported by the xts package. At present, objects inheriting from the 'ts' class are returned as xts objects. This is to make the results more visually appealling and informative. All xts objects can be converted to class ts with as.ts if that is desirable.

The first and final row of returned object will have the period return to last date, i.e. this week/month/quarter/year return to date even if the start/end is not the start/end of the period. Leading period calculations can be suppressed by setting leading=FALSE.

periodReturn(QQQQ,period='yearly',subset='2003')  # returns year 2003

rm(QQQQ)

## End(Not run)
```

---

quantmod-class                 *Class "quantmod"*

---

## Description

Objects of class quantmod help to manage the process of model building within the quantmod package. Created automatically by a call to specifyModel they carry information to be used by a variety of accessor functions and methods.

## Objects from the Class

Objects can be created by calls of the form new("quantmod", ...).

Normally objects are created as a result of a call to specifyModel.

## Slots

model.id: Object of class "character" ~~

model.spec: Object of class "formula" ~~

model.formula: Object of class "formula" ~~

model.target: Object of class "character" ~~

model.inputs: Object of class "character" ~~

build.inputs: Object of class "character" ~~

symbols: Object of class "character" ~~

product: Object of class "character" ~~

price.levels: Object of class "zoo" ~~

training.data: Object of class "Date" ~~

build.date: Object of class "Date" ~~

fitted.model: Object of class "ANY" ~~

model.data: Object of class "zoo" ~~

quantmod.version: Object of class "numeric" ~~

**Methods**

No methods defined with class "quantmod" in the signature.

**Author(s)**

Jeffrey A. Ryan

**Examples**

```
showClass("quantmod")
```

---

quantmod.OHLC                    *Create Open High Low Close Object*

---

**Description**

Coerce an object with the apporpriate columns to class quantmod.OHLC, which extends zoo.

**Usage**

```
as.quantmod.OHLC(x,
                 col.names = c("Open", "High",
                               "Low", "Close",
                               "Volume", "Adjusted"),
                 name = NULL, ...)
```

**Arguments**

| | |
|---|---|
| x | object of class zoo |
| col.names | suffix for columns |
| name | name to attach unique column suffixes to, defaults to the object name |
| ... | additional arguments (unused) |

**Details**

quantmod.OHLC is actually just a renaming of an object of class zoo, with the convention of NAME.Open, NAME.High, ... for the column names.

Additionally methods may be written to handle or check for the above conditions within other functions - as is the case within the **quantmod** package.

**Value**

An object of class c('quantmod.OHLC','zoo')

**Author(s)**

Jeffrey A. Ryan

saveChart                    *Save Chart to External File*

---

## Description

Save selected chart to an external file.

## Usage

```
saveChart(.type = "pdf", ..., dev = dev.cur())
```

## Arguments

| | |
|---|---|
| .type | type of export. See Details. |
| ... | arguments to pass to device |
| dev | which device should be exported |

## Details

This function wraps the base R function pdf, postscript, png, jpeg, and bitmap. The .type argument must specify which device driver is desired.

The currently active device is used if dev is missing. The result is an exact copy (within the device limits) of the chart specified.

The name of the resultant file is derived from the name of the chart, with the appropriate extension appended. (from .type). Specifying the appropriate device file/filename will override this name.

The caller may specify any parameters that are valid for the device called. Internally, effort is made to match the dimensions of the device being used to create the output file. User supplied dimensions will override this internal calculation.

## Value

A file in the current directory (default) matching the type of the output requested.

## Note

As this uses do.call internally to create the new output device, any device that makes use of R conventions should be acceptable as a value for .type

addBBands()

saveChart('pdf')
saveChart('pdf', width=13)

## End(Not run)
```

---

setSymbolLookup            *Manage Symbol Lookup Table*

---

## Description

Create and manage Symbol defaults lookup table within R session for use in getSymbols calls.

## Usage

```
setSymbolLookup(...)
getSymbolLookup(Symbols=NULL)
unsetSymbolLookup(Symbols,confirm=TRUE)

saveSymbolLookup(file,dir="")
loadSymbolLookup(file,dir="")
```

## Arguments

| | |
|---|---|
| ... | name=value pairs for symbol defaults |
| Symbols | name of symbol(s) |
| confirm | warn before deleting lookup table |
| file | filename |
| dir | directory of filename |

**Details**

Use of these functions allows the user to specify a set of default parameters for each Symbol to be loaded.

Different sources (e.g. yahoo, MySQL, csv), can be specified for each Symbol of interest. The sources must be *valid* getSymbols methods - see getSymbols for details on which methods are available, as well as how to add additional methods.

The argument list to setSymbolLookup is simply the unquoted name of the Symbol matched to the desired default source, or list of Symbol specific parameters.

For example, to signify that the stock data for Sun Microsystems (JAVA) should be downloaded from Yahoo! Finance, one would call setSymbolLookup(JAVA='yahoo') or setSymbolLookup(JAVA=list(src='yahoo')

It is also possible to specify additional, possibly source specific, lookup details on a per symbol basis. These include an alternate naming convention (useful for sites like Yahoo! where certain non-traded symbols are prepended with a caret, or more correctly a curcumflex accent. In that case one would specify setSymbolLookup(DJI=list(name="^DJI",src="yahoo"))) as well as passed parameters like dbname and password for database sources. See the specific getSymbols function related to the source in question for more details of each implementation.

If a single named list is passed into the function without naming the list as a parameter, the names of this list will be presumed to be symbol names to be added to the current list of symbols.

All changes are made to the current list, and will persist *only* until the end of the session. To *always* use the same defaults it is necessary to call setSymbolLookup with the appropriate parameters from a startup file (e.g. .Rprofile) or to use saveSymbolLookup and loadSymbolLookup to save and restore lookup tables.

To unset a specific Symbol's defaults, simply assign NULL to the Symbol.

**Value**

Called for its side effects, the function changes the options value for the specified Symbol through a call to options(getSymbols.sources=...)

**Note**

Changes are *NOT* persistent across sessions, as the table is stored in the session options by default.

This *may* change to allow for an easier to manage process, as for now it is designed to minimize the clutter created during a typical session.

```
setSymbolLookup(QQQQ='yahoo',DIA='MySQL')
getSymbolLookup('QQQQ')
getSymbolLookup(c('QQQQ','DIA'))

## Not run:
## Will download QQQQ from yahoo
## and load DIA from MySQL
getSymbols(c('QQQQ','DIA'))

## End(Not run)

## Use something like this to always retrieve
## from the same source

.First <- function() {
  require(quantmod,quietly=TRUE)
  quantmod::setSymbolLookup(JAVA="MySQL")
}

## OR

saveSymbolLookup()
loadSymbolLookup()
```

setTA                     *Manage TA Argument Lists*

## Description

Used to manage the TA arguments used inside chartSeries calls.

## Usage

```
setTA(type = c("chartSeries", "barChart", "candleChart"))

listTA(dev)
```

## Arguments

| | |
|---|---|
| type | the function to apply defaults TAs to |
| dev | the device to display TA arguments for |

## Details

setTA and unsetTA provide a simple way to reuse the same TA arguments for multiple charts. By default all charting functions will be set to use the current chart's defaults.

It is important to note that the *current* device will be used to extract the list of TA arguments to apply. This is done with a call to listTA internally, and followed by calls to setDefaults of the appropriate functions.

An additional way to set default TA arguments for subsequent charts is via `setDefaults`. See the examples.

#### Value

Called for its side-effect of setting the default TA arguments to quantmod's charting functions.

#### Note

Using `setDefaults` directly will require the vector of default TA calls to be wrapped in a call to `substitute` to prevent unintended evaluations; *OR* a call to `listTA` to get the present TA arguments. This last approach is what `setTA` wraps.

#### Examples

```
## Not run:
listTA()
setTA()

# a longer way to accomplish the same
setDefaults(chartSeries,TA=listTA())
setDefaults(barCart,TA=listTA())
setDefaults(candleChart,TA=listTA())

setDefaults(chartSeries,TA=substitute(c(addVo(),addBBands())))

## End(Not run)
```

---

specifyModel                    *Specify Model Formula For quantmod Process*

---

#### Description

Create a single reusable model specification for subsequent buildModel calls. An object of class quantmod is created that can be then be reused with different modelling methods and parameters. No data frame is specified, as data is retrieved from potentially multiple environments, and internal calls to getSymbols.

## Usage

```
specifyModel(formula, na.rm=TRUE)
```

## Arguments

formula         an object of class `formula` (or one that can be coerced to that class): a symbolic
                description of the model to be fitted. The details of model specifcation are given
                under Details.

na.rm           remove all incomplete rows.

## Details

Models are specified through the standard formula mechanism.

As financial models may include a variety of financial and economic indicators, each differing in
source, frequency, and/or class, a single mechanism to specify sources is included within a call to
specifyModel. See `getModelData` for details of how this process works.

Currently, objects of class quantmod.`OHLC`, `zoo`, `ts` and `its` are supported within the model for-
mula.

All symbols are first retrieved from the global environment, without inheritence. If an object is
not found in the global environment, it is added to a list of objects to load through the `getSymbols`
function. getSymbols retrieves each object specified by using information as to its location specified
apriori via `setDefaults` or `setSymbolLookup`.

Internally all data is coerced to `zoo`,`data.frame`, or `numeric` classes.

## Value

Returns an object of class quantmod. Use `modelData` to extract full data set as `zoo` object.

## Note

It is possible to include any supported series in the formula by simply specifying the object's sym-
bol. See *Details* for a list of currently supported classes.

Use getSymbols.skeleton to create additional methods of data sourcing, e.g. from a proprietary
data format or currently unimplemented source (Bloomberg, Oracle).

See getSymbols.MySQL and getSymbols.yahoo for examples of adding additional functionality

TA                              *Add Technical Indicator to Chart*

---

## Description

Functions to add technical indicators to a chart.

## Details

The general mechanism to add technical analysis studies or overlays to a financial chart created with chartSeries.

Functionality marked with a '*' is via the **TTR** package.

General TA charting tool functions:

- addTAadd data as custom indicator
- dropTAremove technical indicator
- moveTAmove a technical indicator
- swapTAswap two technical indicators

Current technical indicators include:

- addADXadd Welles Wilder's Directional Movement Indicator*
- addATRadd Average True Range *
- addAroonadd Aroon Indicator *
- addAroonOscadd Aroon Oscillator *
- addBBands:add Bollinger Bands *
- addCCIadd Commodity Channel Index *
- addCMFadd Chaiken Money Flow *
- addChADadd Chaiken Accumulation Distribution Line *
- addChVoladd Chaiken Volatility *
- addCMOadd Chande Momentum Oscillator *
- addDEMAadd Double Exponential Moving Average *
- addDPOadd Detrended Price Oscillator *
- addEMAadd Exponential Moving Average *

- addEMVadd Arm's Ease of Movement *
- addEnvelopeadd Moving Average Envelope
- addEVWMAadd Exponential Volume Weighted Moving Average *
- addExpiryadd options or futures expiration lines
- addKSTadd Know Sure Thing *
- addLinesadd line(s)
- addMACD:add Moving Average Convergence Divergence *
- addMFIadd Money Flow Index *
- addMomentumadd Momentum *
- addOBVadd On-Balance Volume *
- addPointsadd point(s)
- addROC:add Rate of Change *
- addRSIadd Relative Strength Indicator *
- addSARadd Parabolic SAR *
- addSMAadd Simple Moving Average *
- addSMIadd Stochastic Momentum Index *
- addTDIadd Trend Direction Index *
- addTRIXadd Triple Smoothed Exponential Oscillator *
- addVoadd Volume if available
- addVolatilityadd volatility *
- addWMAadd Weighted Moving Average *
- addWPRadd Williams Percent R *
- addZigZagadd Zig Zag *
- addZLEMAadd ZLEMA *

See the individual functions for specific implementation and argument details. Details of the underlying TTR implementations can be found in **TTR**.

The primary changes between the add*** version of an indicator and the **TTR** base function is the absense of the data argument in the former.

Notable additions include on, `with.col`.

**Value**

Called for its side effects, an object to class chobTA will be returned invisibly. If called from the R command line the method will draw the appropriate indicator on the current chart.

**Note**

Calling any of the above methods from within a function or script will generally require them to be wrapped in a `plot` call as they rely on the context of the call to initiate the actual charting addition.

| tradeModel | *Simulate Trading of Fitted quantmod Object* |
|------------|----------------------------------------------|

---

## Description

Simulated trading of fitted quantmod object. Given a fitted model, tradeModel calculates the signal generated over a given historical period, then applies specified `trade.rule` to calculate and return a `tradeLog` object. Additional methods can then be called to evaluate the performance of the model's strategy.

## Usage

```
tradeModel(x,
           signal.threshold = c(0, 0),
           leverage = 1,
           return.model = TRUE,
           plot.model = FALSE,
           trade.dates = NULL,
           exclude.training = TRUE,
           ret.type = c("weeks", "months", "quarters", "years"),
           ...)
```

## Arguments

x                 a quantmod object from `buildModel`

signal.threshold

                  a numeric vector describing simple lower and upper thresholds before trade occurs

leverage          amount of leverage to apply - currently a constant

return.model      should the full model be returned?

plot.model        plot the model?

trade.dates       specific trade interval - defaults to full dataset

exclude.training

                  exclude the period trained on?

ret.type          a table of period returns

...               additional parameters needed by the underlying modelling function, if any

**Details**

Still highly experimental and changing. The purpose is to apply a newly contructed model from
`buildModel` to a new dataset to investigate the model's trading potential.

At present all parameters are very basic. The near term changes include allowing for a trade.rule
argument to allow for a dynamic trade rule given a set of signals. Additional the application of
variable leverage and costs will become part of the final structure.

Any suggestions as to inclusions or alterations are appreciated and should be directed to the main-
tainer of the package.

**Value**

A quantmodResults object

zoomChart                        *Change Zoom Level Of Current Chart*

---

**Description**

Using **xts** style date subsetting, zoom into or out of the current chart.

**Usage**

```
zooom(n=1, eps=2)
zoomChart(subset, yrange=NULL)
```

## Arguments

| | |
|---|---|
| n | the number of interactive view changes per call |
| eps | the distance between clicks to be considered a valid subset request |
| subset | a valid subset string |
| yrange | override y-scale |

## Details

These function allow for viewing of specific areas of a chart produced by `chartSeries` by simply specifying the dates of interest

`zooom` is an interactive chart version of `zoomChart` which utilizes the standard R device interaction tool `locator` to estimate the subset desired. This estimate is then passed to zoomChart for actual redrawing. At present it is quite experimental in its interface and arguments. Its usage entails a call to zooom() followed by the selection of the leftmost and rightmost points desired in the newly zoomed chart. This selection is accomplished by the user left-clicking each extreme point. Two click are required to determine the level of zooming. Double clicking will reset the chart to the full data range. The arguments and internal working of this function are likely to change dramatically in future releases, though its use will likely remain.

Standard format for the `subset` argument is the same as the subsetting for xts objects, which is how the data is stored internally for rendering.

Calling `zoomChart` with no arguments (NULL) resets the chart to the original data.

Examples include '2007' for all of the year 2007, '2007::2008' for years 2007 through 2008, '::2007' for all data from the beginning of the set to the end of 2007, '2007::' all data from the beginning of 2007 through the end of the data. For specifics regarding the level of detail and internal interpretation please see `[.xts`

## Value

This function is called for its side effect - notably changing the perspective of the current chart, and changing its formal subset level. The underlying data attached to the chart is left unchanged.
